 <b>Marwadi University</b> Marwadi Chandarana Group	<b>Marwadi University</b> <b>Faculty of Engineering &amp; Technology</b> <b>Department of Information and Communication Technology</b>	
<b>Subject: Programming With Python (01CT1309)</b>	<b>Aim:</b> Write a program to create, concatenate and print a string and accessing substring from a given string.	
<b>Experiment No: 03</b>	<b>Date:21/07/2025</b>	<b>Enrollment No:92400133037</b>

**Aim:** Write a program to create, concatenate and print a string and accessing substring from a given string.

**IDE:**

Slicing and indexing are two fundamental concepts in Python. They help us access specific elements in a sequence, such as a string or (list and tuple).

**Indexing in Python**

Indexing is the process of accessing an element in a sequence using its position in the sequence (its index). In Python, indexing starts from 0, which means the first element in a sequence is at position 0, the second element is at position 1, and so on. To access an element in a sequence, you can use square brackets [] with the index of the element you want to access.

**Let's consider the following example:**

```
# create a string using double quotes
string1 = "ICT Department"
print(string1)
# create a string using single quotes
string1 = ' ICT Department '
print(string1)
Output
```

Negative Indexing:

Python allows negative indexing for its strings. For example,

string3 = 'ICT Department'

# access 4th last element

print(string3 [-4])

output:

 <b>Marwadi University</b> Marwadi Chandarana Group	<b>Marwadi University</b> <b>Faculty of Engineering &amp; Technology</b> <b>Department of Information and Communication Technology</b>	
<b>Subject: Programming With Python (01CT1309)</b>	<b>Aim:</b> Write a program to create, concatenate and print a string and accessing substring from a given string.

## Slicing in Python

Slicing is the process of accessing a sub-sequence of a sequence by specifying a starting and ending index. In Python, you perform slicing using the colon: operator. The syntax for slicing is as follows:

Example:

sequence[start\_index:end\_index]

 <b>Marwadi University</b> Marwadi Chandarana Group	<b>Marwadi University</b> <b>Faculty of Engineering &amp; Technology</b> <b>Department of Information and Communication Technology</b>	
<b>Subject: Programming With Python (01CT1309)</b>	<b>Aim:</b> Write a program to create, concatenate and print a string and accessing substring from a given string.	
<b>Experiment No: 03</b>	<b>Date:21/07/2025</b>	<b>Enrollment No:92400133037</b>

where start\_index is the index of the first element in the sub-sequence and end\_index is the index of the last element in the sub-sequence (excluding the element at the end\_index). To slice a sequence, you can use square brackets [] with the start and end indices separated by a colon.

For example,

```
string4 = 'ICT Department'
```

```
# access character from 1st index to 3rd index
```

```
print(string4[1:4])
```

Output:

```

14  #slicing
15  st4='ICT Department'
16  print(st4[1:4])
17  print(st4[:2])
18  print(st4[2:])
19

```

```

CT
IC
T Department

```

You can also omit either the start\_index or the end\_index in a slice to get all the elements from the beginning or end of the sequence. For example:

```
print(string4[:2])
```

```
print(string4[2:])
```

output:

```

14  #slicing
15  st4='ICT Department'
16  print(st4[1:4])
17  print(st4[:2])
18  print(st4[2:])
19

```

```

CT
IC
T Department

```

 <b>Marwadi University</b> Marwadi Chandarana Group	<b>Marwadi University</b> <b>Faculty of Engineering &amp; Technology</b> <b>Department of Information and Communication Technology</b>	
<b>Subject: Programming With Python (01CT1309)</b>	<b>Aim:</b> Write a program to create, concatenate and print a string and accessing substring from a given string.	
<b>Experiment No: 03</b>	<b>Date:21/07/2025</b>	<b>Enrollment No:92400133037</b>

In the first line of the above code, we have used slicing to get all the elements from the beginning of string4 up to (but not including) the element at index 2. In the second line, we have used slicing to get all the elements from index 2 to the end of string4.

### Python Strings are Immutable

In Python, strings are immutable. That means the characters of a string cannot be changed. For example,

```
message = 'ICT Department'
```

```
message[0] = 'H'
```

```
print(message)
```

Output:

```
19
20 #strings are immutable
21 #mes='ict department'
22 #mes[0]='h'
23 #print(mes)--type error--does not support assignment
24
```

However, we can assign the variable name to a new string. For example,

```
message = 'ICT'
```

```
# assign new string to message variable
```

```
message = 'ICT Department'
```

```
print(message)
```

### Python Multiline String

We can also create a multiline string in Python. For this, we use triple double quotes `"""` or triple single quotes `'`. For example,

```
# multiline string
```

```
message = """
```

```
ICT
```

```
Department
```

```
3EK1
```

```
"""
```

```
print(message)
```

Output:

 <b>Marwadi University</b> Marwadi Chandarana Group	<b>Marwadi University</b> <b>Faculty of Engineering &amp; Technology</b> <b>Department of Information and Communication Technology</b>	
<b>Subject: Programming With Python (01CT1309)</b>	<b>Aim:</b> Write a program to create, concatenate and print a string and accessing substring from a given string.	
<b>Experiment No: 03</b>	<b>Date:21/07/2025</b>	<b>Enrollment No:92400133037</b>

```

25  #multiline string
26  mess=""
27  ICT
28  Department
29  3ek1
30  ""
31  print(mess)

```

PROBLEMS   OUTPUT   DEBUG CONSOLE   TERMINAL

✓ **TERMINAL**

```

ICT
Department
3ek1

```

## Python String Operations

Many operations can be performed with strings, which makes it one of the most used data types in Python.

### 1. Compare Two Strings

For example,

```
str1 = "ICT"
```

```
str2 = "Department"
```

```
str3 = "3EK1"
```

```
# compare str1 and str2
```

```
print(str1 == str2)
```

```
# compare str1 and str3
```

```
print(str1 == str3)
```

Output:

 <b>Marwadi University</b> Marwadi Chandarana Group	<b>Marwadi University</b> <b>Faculty of Engineering &amp; Technology</b> <b>Department of Information and Communication Technology</b>	
<b>Subject: Programming With Python (01CT1309)</b>	<b>Aim:</b> Write a program to create, concatenate and print a string and accessing substring from a given string.	
<b>Experiment No: 03</b>	<b>Date:21/07/2025</b>	<b>Enrollment No:92400133037</b>

```
lab3 > string_op.py > ...
1  #compare
2  st1="ICT"
3  st2="Department"
4  st3="3EK1"
5
6  print(st1==st2)#false
7  print(st1==st3)#false
8
```

```
PS G:\sem-3\python_lab> python -u "g:\sem-3\python_lab\lab3\string_op.py"
False
False
```

## 2. Join Two or More Strings

In Python, we can join (concatenate) two or more strings using the + operator.

```
greet = "ICT"
name = "Department"
# using + operator
result = greet + name
print(result)
```

Output:

```
9
10 #concatenate
11 greet='ICT'
12 name="Department"
13 print(greet+name)
14
False
ICTDepartment
```

## Python String Length

In Python, we use the len() method to find the length of a string. For example,

```
greet = 'ICT'
# count length of greet string
print(len(greet))
```

Output:

 <b>Marwadi University</b> Marwadi Chandarana Group	<b>Marwadi University</b> <b>Faculty of Engineering &amp; Technology</b> <b>Department of Information and Communication Technology</b>	
<b>Subject: Programming With Python (01CT1309)</b>	<b>Aim:</b> Write a program to create, concatenate and print a string and accessing substring from a given string.	
<b>Experiment No: 03</b>	<b>Date:21/07/2025</b>	<b>Enrollment No:92400133037</b>

```
15 #length
16 print(len(greet))
```

```
3
```

### String Membership Test

We can test if a substring exists within a string or not, using the keyword in.

```
print('a' in 'program')
```

```
print('at' not in 'battle')
```

Output:

```
#membership
print('a' in 'program')#true
print('at' not in 'battle')#false
```

```
True
False
```

### Methods of Python String

#### Python String upper()

The upper() method converts all lowercase characters in a string into uppercase characters and returns it.

```
message = 'python is fun'
```

```
# convert message to uppercase
```

```
print(message.upper())
```

Output:

```
20 print(name.upper())
```

```
False
DEPARTMENT
```

#### Python String lower()

The lower() method converts all uppercase characters in a string into lowercase characters and returns it.

```
message = 'PYTHON IS FUN'
```

```
# convert message to lowercase
```

```
print(message.lower())
```

Output:

 <b>Marwadi University</b> Marwadi Chandarana Group	<b>Marwadi University</b> <b>Faculty of Engineering &amp; Technology</b> <b>Department of Information and Communication Technology</b>	
<b>Subject: Programming With Python (01CT1309)</b>	<b>Aim:</b> Write a program to create, concatenate and print a string and accessing substring from a given string.	
<b>Experiment No: 03</b>	<b>Date:21/07/2025</b>	<b>Enrollment No:92400133037</b>

```
21 print(name.lower())
```

```
department
```

### Python String replace()

The replace() method replaces each matching occurrence of a substring with another string.

```
text = 'CE Department'
```

```
replaced_text = text.replace('CE', 'ICT')
```

```
print(replaced_text)
```

Output:

```
#replace()
text='CE Department'
replaced_text=text.replace('CE','ICT')
#replaced_text=text.replace('ce','ict')--error will not
print(replaced_text)
```

```
ICT Department
```

### Python String find()

The find() method returns the index of first occurrence of the substring (if found). If not found, it returns -1.

```
message = 'Python is a fun programming language'
```

```
# check the index of 'fun'
```

```
print(message.find('fun'))
```

Output:

```
11 #find()
12 mess='Python is a fun programming language fun'
13 print(mess.find('fun'))
```

```
12
```

### Python String rstrip()

The rstrip() method returns a copy of the string with trailing characters removed (based on the string argument passed).

```
title = 'Python Programming '
```

```
result = title.rstrip()
```

 <b>Marwadi University</b> Marwadi Chandarana Group	<b>Marwadi University</b> <b>Faculty of Engineering &amp; Technology</b> <b>Department of Information and Communication Technology</b>	
<b>Subject: Programming With Python (01CT1309)</b>	<b>Aim:</b> Write a program to create, concatenate and print a string and accessing substring from a given string.	
<b>Experiment No: 03</b>	<b>Date:21/07/2025</b>	<b>Enrollment No:92400133037</b>

```
print(result)
```

Output:

```
14
15 #rstrip()
16 title='Python Programming g'
17 print(title.rstrip('g'))
18
```

```
Python Programming
```

### Python String split()

The split() method breaks down a string into a list of substrings using a chosen separator.

```
text = 'Python is fun'
```

```
# split the text from space
```

```
print(text.split())
```

```
19 #split
20 text='Python is fun'
21 print(text.split())
22
```

```
Python Programming
['Python', 'is', 'fun']
```

### Python String startswith()

The startswith() method returns True if a string starts with the specified prefix(string). If not, it returns False.

```
message = 'Python is fun'
```

```
# check if the message starts with Python
```

```
print(message.startswith('Python'))
```

Output:

```
23 #startswith()
24 mess='Python is fun'
25 print(mess.startswith('python'))
26 print(mess.startswith('Python'))
27
```

```
False
True
```

### Python String isnumeric()

The isnumeric() method checks if all the characters in the string are numeric.

 <b>Marwadi University</b> Marwadi Chandarana Group	<b>Marwadi University</b> <b>Faculty of Engineering &amp; Technology</b> <b>Department of Information and Communication Technology</b>	
<b>Subject: Programming With Python (01CT1309)</b>	<b>Aim:</b> Write a program to create, concatenate and print a string and accessing substring from a given string.	
<b>Experiment No: 03</b>	<b>Date:21/07/2025</b>	<b>Enrollment No:92400133037</b>

```
pin = "523"
# checks if every character of pin is numeric
print(pin.isnumeric())
Output:
```

```
28 #isnumeric()
29 pin="523"
30 print("\n",pin.isnumeric())
31
```

True

### Python String index()

The index() method returns the index of a substring inside the string (if found). If the substring is not found, it raises an exception.

```
text = 'Python is fun'
# find the index of is
result = text.index('is')
print(result)
Output:
```

```
32 #index()
33 text='Python is fun'
34 print(text.index('is'))
35 #print(text.index('IS'))--value Error-substring not found
```

7

### Python String Formatting (f-Strings)

Python f-Strings makes it easy to print values and variables. For example,

```
name = 'Cathy'
country = 'UK'
print(f'{name} is from {country}')
Output:
```

 <b>Marwadi University</b> Marwadi Chandarana Group	<b>Marwadi University</b> <b>Faculty of Engineering &amp; Technology</b> <b>Department of Information and Communication Technology</b>	
<b>Subject: Programming With Python (01CT1309)</b>	<b>Aim:</b> Write a program to create, concatenate and print a string and accessing substring from a given string.	
<b>Experiment No: 03</b>	<b>Date:21/07/2025</b>	<b>Enrollment No:92400133037</b>

```

37  #f-strings
38  name='Cathy'
39  country='UK'
40  print(f'\n{name} is from {country}')
41

```

```
Cathy is from UK
```

### Python Raw String

Python strings become raw strings when they are prefixed with r or R, such as r'...' and R'...'. Raw strings treat backslashes () as literal characters. Raw strings are useful for strings with a lot of backslashes, like regular expressions or directory paths.

```
str = "This is a \n normal string example"
```

```
print(str)
```

```
raw_str = r"This is a \n raw string example"
```

```
print(raw_str)
```

Output

```

42  #raw string
43  str="This is a \n normal string example"
44  print(str)
45  print(r"This is a \n raw string example")

```
